

Schema Conjunction via Inclusion

Define two simple schemas.

A
$x : \mathbb{N}$

B
$y : \mathbb{N}$

Schema AB includes both A and B , adds a third component, and uses the schemas as predicates in the where clause.

AB
A
B
$z : \mathbb{N}$
$A \wedge B$
$z = x + y$

Typed Disambiguation

A critical disambiguation: $\text{count}, \text{count}' : \mathbb{N}$ is a typed declaration (two variables sharing a type), NOT an inclusion of schema count . The scan-ahead rule detects the colon and routes to the typed-declaration path.

$TwoNames$
$\text{count} : \mathbb{N}$
$\text{limit} : \mathbb{N}$
$\text{count} \leq \text{limit}$

But Counter alone on its own line (no colon) is a bare schema inclusion:

$HasCounter$
$TwoNames$
$\text{extra} : \mathbb{N}$
